you can use the 'row number' function for the following use cases:

To determine the top 10 selling products out of a large variety of products

To determine the top three winners in a car race

To find the top five areas in different cities in terms of GDP growth

The main advantage of the 'row number' function over all the other types of rank functions is that it returns unique values

```
/*
```

So, as you learnt in this video, the same window can be used to define multiple 'over' clauses.

You can define the window once, give it a name and then refer to the name in the 'over' clauses.

A named window makes it easier to experiment with multiple window definitions and observe their effects on the query result

You only need to modify the window definition in the 'window' clause, rather than using multiple 'over' clause definitions.

Rank functions: The different types of rank functions are as follows:

RANK(): Rank of the current row within its partition, with gaps

DENSE\_RANK(): Rank of the current row within its partition, without gaps

PERCENT\_RANK(): Percentage rank value; it will always lie between 0 and 1

ROW\_NUMBER(): Assigns unique numeric values to each row, starting from 1

Named windows: A named window makes it easier to define and reuse multiple window functions.

Order of SQL statements: The order in which the various SQL statements appear in a query is as follows:

```

SELECT
FROM
JOIN
WHERE
GROUP BY
HAVING
WINDOW
ORDER BY

```

Frames: Frames are used to subset a set of consecutive rows and calculate moving averages.

A query using a frame has multiple components as shown in the diagram given below.

Lead and lag functions: These functions are used to compare a row value with the next or the previous row value. The syntax for the 'lead' function is as follows:

`*/`
